

Private execution for autonomous agents on Solana.

Give an AI agent a goal—not unrestricted access to your wallet.

[Solana Devnet](#)[Token-2022](#)[AISA Integration](#)[Student Group](#)

Agent autonomy currently comes with two unsafe defaults.

01 / PUBLIC BY DEFAULT

Every payment becomes permanent intelligence.

Balances, payment amounts, supplier pricing, operating cadence, and treasury runway can be profiled once an agent wallet is linked to its owner.

02 / PROMPT AS POLICY

“Do not overspend” is guidance, not authority.

A prompt-injected or malfunctioning model can ignore a textual limit when the same agent still controls an unrestricted signing path.

Owners should be able to delegate an outcome without publishing their finances or surrendering root control.

Agency separates intelligence from authority.

AI AGENT

Plans the work

Turns a natural-language goal into observations, verified tools, decisions, clarification, and honest refusal.

POLICY LAYER

Controls what may happen

Payment details must match the owner's goal, imported vendor profile, custody path, and spending authorization.

CONFIDENTIAL SETTLEMENT

Protects financial values

Token-2022 Confidential Transfer encrypts the payment amount and confidential token balances on Solana.

The model decides what to do. The policy decides what it is allowed to do.

One owner goal becomes a verified payment workflow.

Agent intelligence, external data, and value authority stay separate.

A live execution graph—not a decorative blockchain diagram.

- ✓ Goal-driven node expansion
- ✓ Verified tool-result nodes
- ✓ AISA attribution and call metrics
- ✓ Public and owner views
- ✓ Clarification and refusal states

Confidential does not mean untraceable.

DATA	CURRENT PROTECTION	WHAT A PUBLIC OBSERVER LEARNS
Transfer amount	Encrypted on-chain	Plaintext amount is absent from recipient account bytes.
Confidential token balance	Encrypted on-chain	Balance remains ciphertext without the authorized key.
Public application view	Structurally redacted	Public DTO contains no goal, amount, balance, or owner-only reasoning.
Transaction metadata	Still public	Existence, accounts, mint, timing, fees, and program interaction remain visible.
Browser policy limits	Currently public	Encrypted-limit verification exists separately; it is not the primary browser flow yet.

External intelligence before consequential actions.

Market-data cross-check

Compares an AISA/CoinGecko reference with an independent Solana market source before the agent relies on a price.

Counterparty research

Uses AISA/Tavily to find outages, exploits, depegs, or other external conditions that chain state cannot answer.

AISA credentials stay behind server-side proxy routes. Every completed sponsor call is visibly attributed in the graph.

Working devnet proof, backed by reproducible tests.

Vitest

Privacy turns agent payments into usable financial infrastructure.

Individuals

Subscriptions, data purchases, and personal automation without publishing a financial profile.

Startups and SMEs

SaaS, API, compute, and supplier payments without exposing private pricing.

DAO treasuries

Contributor payouts and grants with bounded automation and owner recovery.

Agent platforms

A reusable authority and privacy layer for autonomous on-chain workflows.

Privacy is not a security gimmick. It lowers the trust cost of moving real workflows on-chain.

Move from a strong prototype to a production privacy boundary.

NOW

Functional prototype

- Real confidential devnet payments
- Agent Graph and AISA tools
- Policy-controlled custody path
- Public and owner views

NEXT

Production readiness

- Primary browser encrypted-limit flow
- Production RPC and deployment
- Lower proof latency
- Named user pilots

VISION

Private agent infrastructure

- Reusable wallet-level capability layer
- Shielded ownership and execution
- Scoped auditor access
- Multiple agent frameworks
